

**Amendments to the Claims:**

Please cancel claims 2, 5, 14, and 17. Please amend claims 1 and 13 as follows.

This listing of claims replaces all prior versions, and listings, of claims in the application.

**Listing of claims:**

1. (currently amended) An imaging apparatus comprising:  
first signal processing means including a first analog-to-digital converter for converting an analog image signal into a first digital signal for partitioning the level of [[an]] the analog image signal into a plurality of sections, a gain selector for selecting a corresponding gain from a plurality of different gains according to each of the plurality of sections, and an amplifier for amplifying the analog image signal by [[a]] the plurality of gains according to each of the plurality of sections, at least two of the sections having different corresponding gains; and  
second signal processing means including a second analog-to-digital converter for converting the analog image signal amplified by the plurality of different gains into a first second digital signal, and a gamma corrector for non-linearly gamma-correcting the first second digital signal according to each section of the plurality of sections on which the amplification of the analog image signal by the first signal processing means is based.
2. (canceled)
3. (original) The imaging apparatus of claim 2, wherein the plurality of different gains are provided by a microcomputer.
4. (original) The imaging apparatus of claim 2, wherein the plurality of different gains are approximately inversely proportional to the luminance level of the analog image signal.
5. (canceled)

6. (original) The imaging apparatus of claim 1, further comprising a chrominance controller for controlling chrominance gain of the non-linearly gamma corrected digital output of the second signal processing means.

7. (original) The imaging apparatus of claim 6, wherein the chrominance controller comprises:

- a low pass filter for passing a low-frequency component of the non-linearly gamma corrected digital output of the second means, to output a luminance signal;

- a chrominance gain selector for partitioning the level of the luminance signal into a plurality of second sections, and for selectively outputting a corresponding second gain among a plurality of different second gains according to each section;

- a high pass filter for passing a high frequency component of the non-linearly gamma corrected digital output of the second means, to output a chrominance signal;

- a multiplier for multiplying the chrominance signal by the corresponding second gain from the chrominance gain selector;

- an adder for adding the output of the multiplier to the luminance signal;

- a divider for dividing the output of the adder by approximately 2; and

- a clipper for outputting a digital 0 if the output of the divider is less than 0, and for outputting the maximum value of the output of the second signal processing means if the output of the divider is greater than the maximum value of the output of the second signal processing means.

8. (original) The imaging apparatus of claim 7, wherein the plurality of different second gains are approximately inversely proportional to the level of the luminance signal.

9. (original) An imaging apparatus comprising:

- an amplifier for amplifying an analog image signal by a predetermined gain;

- an analog-to-digital converter for converting the amplified analog image signal into a digital signal;

a chrominance controller for controlling chrominance gain of the converted output of the analog-to-digital converter; and

a digital signal processor for processing the output of the chrominance controller.

10. (original) The imaging apparatus of claim 9, wherein the chrominance controller comprises:

a low pass filter for passing a low-frequency component of the converted output of the analog-to-digital converter, to output a luminance signal;

a chrominance gain selector for dividing the level of the luminance signal into a plurality of sections, and for selectively outputting a corresponding gain among the plurality of different gains according to each section;

a high pass filter for passing a high frequency component of the converted output of the analog-to-digital converter, to output a chrominance signal;

a multiplier for multiplying the chrominance signal by the corresponding gain output from the chrominance gain selector;

an adder for adding the output of the multiplier to the luminance signal;

a divider for dividing the output of the adder by a factor; and

a clipper for outputting a digital 0 if the output of the divider is less than 0, and for outputting the maximum value of the output of the analog-to-digital converter if the output of the divider is greater than the maximum value of the output of the analog-to-digital converter.

11. (original) The imaging apparatus of claim 10, wherein the plurality of different gains are approximately inversely proportional to the level of the luminance signal.

12. (original) The imaging apparatus of claim 10, wherein the factor is approximately 2.

13. (currently amended) An image signal processing method comprising:  
converting the analog image signal into a first digital signal for partitioning the level of an  
analog image signal into a plurality of sections, selecting a corresponding gain among the  
plurality of different gains according to each of the plurality of sections and amplifying  
the image signal by a plurality of different gains according to each of the plurality of sections, at  
least two of the sections having different corresponding gains; and

converting the image signal amplified by the plurality of different gains into a first second  
digital signal, and non-linearly gamma-correcting the first second digital signal according to each  
section of the plurality of sections on which the amplification of the analog image signal ~~by the~~  
~~first signal processing means~~ is based.

14. (canceled)

15. (original) The method of claim 14, wherein the plurality of different gains are  
provided by a microcomputer.

16. (original) The method of claim 14, wherein the plurality of different gains are  
approximately inversely proportional to the luminance level of the analog image signal.

17. (canceled)

18. (original) The method of claim 13, further comprising controlling chrominance  
gain of the non-linearly gamma-corrected second digital signal.

19. (previously presented) The method of claim 18, wherein controlling comprises:  
passing a low-frequency component of the non-linearly gamma-corrected digital signal, to  
output a luminance signal;

partitioning the level of the luminance signal into a plurality of second sections, and  
selecting a corresponding second gain among a plurality of different second gains according to

each second section;

passing a high-frequency component of the non-linearly gamma-corrected digital signal,  
to output a chrominance signal;

multiplying the chrominance signal by the corresponding selected second gain;

adding the result of the multiply to the luminance signal;

dividing the result of the add by approximately 2; and

clipping to 0 if the result of the division is less than 0, and clipping to the maximum value  
of the gamma-corrected digital signal if the result of the division is greater than the maximum  
value of the gamma-corrected digital signal, and outputting the result.

20. (original) The method of claim 19, wherein the plurality of second gains are  
approximately proportional to the luminance level of the analog image signal.
